

Package ‘errorlocate’

December 30, 2016

Type Package

Title Locate Errors with Validation Rules

Version 0.1.2

Date 2016-12-29

Description Errors in data can be located and removed using validation rules from package 'validate'.

License GPL-3

errorlocate-package *Find errors in data given a set of validation rules.*

Description

Find errors in data given a set of validation rules. The `errorlocate` helps to identify obvious errors in raw datasets.

Details

It works in tandem with the package `validate`. With `validate` you formulate data validation rules to which the data must comply. For example:

```
"age cannot be negative": age >= 0
```

While `validate` can identify if a record is valid or not, it does not identify which of the variables are responsible for the invalidation. This may seem a simple task, but is actually quite tricky: a set of validation rules form a web of dependent variables: changing the value of an invalid record to repair for rule 1, may invalidate the record for rule 2.

`Errorlocate` provides a small framework for record based error detection and implements the Felligi Holt algorithm. This algorithm assumes there is no other information available then the values of a record and a set of validation rules. The algorithm minimizes the (weighted) number of values that need to be adjusted to remove the invalidation.

The `errorlocate` package translates the validation and error localization problem into a mixed integer problem and uses #' a mip solver to find a solution.

add_noise	<i>Add (a small amount of) noise</i>
-----------	--------------------------------------

Description

Utility function to add some small positive noise to weights. This is mainly done to randomly choose between solutions of equal weight. Without adding noise to weights lp solvers may return an identical solution over and over while there are multiple solutions of equal weight. The generated noise is positive to prevent that weights will be zero or negative.

Usage

```
add_noise(x, max_delta = NULL, ...)
```

Arguments

x	numeric vector or matrix. When x is a matrix, the function will be applied to each row of the matrix.
max_delta	when supplied noise will be drawn from $[0, \text{max_delta}]$ otherwise see details
...	currently not used

Details

When no max_delta is supplied, add_noise will use the minimum difference larger than zero divided by the length(x).

Value

numeric vector/matrix with noise applied.

ErrorLocalizer-class	<i>Base class for class locate errors based on rules and data</i>
----------------------	---

Description

ErrorLocalizer can be used as a base class to implement a new error localization algorithm. The derived class must implement two methods: initialize, which is called before any error localization is done and locate which operates upon data. The extra parameter ... can be used to supply algorithmic specific parameters.

errorlocation-class *Error location object*

Description

Errorlocation contains the result of a error detection. Errors can record based or variable based.

- A record based error is restricted within one observation. [errorlocate](#) using the Felligi Holt algorithm assumes errors are record based.
- A variable based error is a flaw in uni- or multivariate distribution. To correct this error multiple observations or the aggregated number should be adjusted.

Details

Current implementation assumes that errors are record based. The error locations can be retrieved using the method [values](#) and are a matrix of rows and columns, with the same dimensions are the `data.frame` that was checked. For errors that are purely column based, or dataset based, error-locations will return a matrix with all rows or cells set to TRUE. The [values](#) return NA for missing values.

Fields

- `$errors`: matrix indicating which values are erroneous (TRUE), missing (NA) or valid (FALSE)
- `$weight`: The total weight per record. A weight of 0 means no errors were detected.

errors_removed *Get location of removed errors from a 'cleaned' data set*

Description

`errors_removed` retrieves the errors detected by [replace_errors](#)

Usage

```
errors_removed(x, ...)
```

Arguments

<code>x</code>	data.frame that was checked for errors
<code>...</code>	not used

Value

[errorlocation-class](#) object

expect_values	<i>expect values</i>
---------------	----------------------

Description

expect values

Usage

```
expect_values(values, weights, ...)
```

Arguments

values	named list of values.
weights	named numeric of equal length as values.
...	not used

FHLocalizer-class	<i>Feligi-Holt Errorlocalizer</i>
-------------------	-----------------------------------

Description

Implementation of the Feligi-Holt algorithm using the ErrorLocalizer base class. Given a set of validation rules and a dataset the Feligi-Holt algorithm finds for each record the smallest (weighted) combination of variables that are erroneous (if any).

Note

Most users do not need this class and can use [locate_errors](#).

errorlocalizer implements feligi holt using a MIP-solver. For problems in which coefficients of the validation rules or the data are too different, you should consider scaling the data.

is_categorical	<i>Check if rules are categorical</i>
----------------	---------------------------------------

Description

Check if rules are categorical

Usage

```
is_categorical(x, ...)
```

Arguments

x	validator object
...	not used

Value

logical indicating which rules are purely categorical/logical

Examples

```
v <- validator( A %in% c("a1", "a2")
               , B %in% c("b1", "b2")
               , if (A == "a1") B == "b1"
               , y > x
               )

is_categorical(v)
```

is_conditional	<i>Check if rules are conditional rules</i>
----------------	---

Description

Check if rules are conditional rules

Usage

```
is_conditional(rules, ...)
```

Arguments

rules	validator object containing validation rules
...	not used

Value

logical indicating which rules are conditional

Examples

```
v <- validator( A %in% c("a1", "a2")
               , B %in% c("b1", "b2")
               , if (A == "a1") x > 1 # conditional
               , if (y > 0) x >= 0 # conditional
               , if (A == "a1") B == "b1" # categorical
               )

is_conditional(v)
```

is_linear

Check which rules are linear rules.

Description

Check which rules are linear rules.

Usage

```
is_linear(x, ...)
```

Arguments

x [validator](#) object containing data validation rules
... not used

Value

logical indicating which rules are (purely) linear.

locate_errors

Locate errors in data

Description

Locate erroneous fields in rows of data using validation rules or a specific errorlocalizer object. This method returns found errors, according to the specified method x. If these errors are to be removed automatically use method [replace_errors](#).

Usage

```
locate_errors(data, x, ...)

## S4 method for signature 'data.frame,validator'
locate_errors(data, x, weight = NULL,
  ref = NULL, ...)

## S4 method for signature 'data.frame,ErrorLocalizer'
locate_errors(data, x, weight = NULL,
  ref = NULL, ...)
```

Arguments

data	data to be checked
x	validation rules or errorlocalizer object to be used for finding possible errors.
...	optional parameter to be used by a specific method
weight	numeric optional weight vector to be used in the error localization.
ref	data.frame optional reference data to be used in the rules checking

Value

[errorlocation-class](#) object describing the errors found.

Examples

```
rules <- validator( profit + cost == turnover
  , cost - 0.6*turnover >= 0
  , cost >= 0
  , profit >= 0
)
data <- data.frame(profit=755, cost=125, turnover=200)
le <- locate_errors(data, rules)

print(le)
summary(le)

v_categorical <- validator( A %in% c("a1", "a2")
  , B %in% c("b1", "b2")
  , if (A == "a1") B == "b1"
)

data <- data.frame(A = c("a1", "a2"), B = c("b2", "b2"))
locate_errors(data, v_categorical)

v_logical <- validator( A %in% c(TRUE, FALSE)
  , B %in% c(TRUE, FALSE)
  , if (A == TRUE) B == TRUE
)
```

```

data <- data.frame(A = TRUE, B = FALSE)
locate_errors(data, v_logical, weight=c(2,1))

# try a condinational rule
v <- validator( married %in% c(TRUE, FALSE), if (married==TRUE) age >= 17 )
data <- data.frame( married = TRUE, age = 16)
locate_errors(data, v, weight=c(married=1, age=2))

```

MipRules-class

Create a mip object from a validator object

Description

Create a mip object from [validator](#) object. This is a utility class that translates a validor object into a mixed integer problem that can be solved. Most users should use [locate_errors](#) which will handle all translation and execution automatically. This class is provided so users can implement or derive a alternative solution.

Methods

The MipRules class contains the following methods:

- `$execute` calls the mip solver to execute the rules.
- `$to_lp`: transforms the object into a `lp_solve` object
- `$is_infeasible` Checks if the current system of mixed integer rules is feasible.
- `$set_values`: set values and weights for variables (determines the objective function).

Examples

```

rules <- validator(x > 1)
mr <- miprules(rules)
mr$to_lp()
mr$set_values(list(x=0, weight=list(x=1)))
mr$execute()

```

replace_errors

Replace erroneous fields with NA or a suggested value

Description

Find erronous fields using [locate_errors](#) and replace these fields automatically with NA or a suggestion that is provided by the error detection algorithm.

Usage

```

replace_errors(data, x, ref = NULL, ..., value = c("NA", "suggestion"))

## S4 method for signature 'data.frame,validator'
replace_errors(data, x, ref = NULL, ...,
  value = c("NA", "suggestion"))

## S4 method for signature 'data.frame,ErrorLocalizer'
replace_errors(data, x, ref = NULL, ...,
  value = c("NA", "suggestion"))

## S4 method for signature 'data.frame,errorlocation'
replace_errors(data, x, ref = NULL, ...,
  value = c("NA", "suggestion"))

```

Arguments

data	data to be checked
x	validator object
ref	optional reference data set
...	these parameters are handed over to locate_errors
value	NA

Value

data with erroneous values removed.

Note

In general it is better to replace the erroneous fields with NA and apply a proper imputation methods. Suggested values from the error localization method may introduce an unwanted bias.

The errors that were removed from the data . frame can be retrieved with the function [errors_removed](#). For more control over error localization see [locate_errors](#).

See Also

[errorlocation-class](#)

Examples

```

library(magrittr)

rules <- validator( profit + cost == turnover
  , cost - 0.6*turnover >= 0
  , cost >= 0
  , profit >= 0
)
data <- data.frame(profit=755, cost=125, turnover=200)

```

```

data_no_error <-
  data %>%
  replace_errors(rules)

# faulty data was replaced with NA
data_no_error

errors_removed(data_no_error)

# a bit more control
error_locations <- locate_errors(data, rules)
data %>%
  replace_errors(error_locations)

```

substitute_ *substitute an existing language object*

Description

substitute an existing language object

Usage

```
substitute_(x, values = list())
```

Arguments

x	expression or language object!
values	list of values

translate_mip_lp *translate linear rules into an lp problem*

Description

translate linear rules into an lp problem

Usage

```
translate_mip_lp(rules, objective = NULL, eps = 0.001)
```

Arguments

rules	mip rules
objective	function
eps	accuracy for equality/inequality
